solid solution formation in spinel based systems proved to be a viable approach to decreasing thermal conductivity samples with systematically varied additions of MgGa_2O_4 to MgAl_2O_4 were prepared and thermal diffusivity was measured using the laser flash technique additionally heat capacity was measured using differential scanning calorimetry and modeled for the MgAl_2O_4 MgGa_2O_4 system at 200 °C thermal conductivity decreased 24% with a 5 mol addition of MgGa_2O_4 to the system the solid solution continued to decrease the thermal conductivity by 13% up to 1000 °C with 5 mol addition the decrease in thermal conductivity ultimately resulted in a decrease in heat flux when applied to a theoretical furnace lining which could lead to energy savings in industrial settings the MgAl_2O_4 Al_2O_3 phase equilibria was investigated to fully understand the system and the thermal properties at elevated temperatures the solvus line between MgAl_2O_4 and Al_2O_3 has been defined at 79.6 wt% Al_2O_3 at 1500 °C 83.0 wt% Al_2O_3 at 1600 °C and 86.5 wt% Al_2O_3 at 1700 °C a metastable region has been identified at temperatures up to 1700 °C which could have significant implications for material processing and properties the spinel solid solution region has been extended to form an infinite solid solution with Al_2O_3 at elevated temperatures a minimum in melting at 1975 °C and a chemistry of 96 wt% Al_2O_3 rather than a eutectic is present thermal properties in the MgAl_2O_4 Al_2O_3 system were investigated in both the single phase solid solution region and the two phase region the thermal diffusivity decreased through the MgAl_2O_4 solid solution region and was at a minimum through the entire metastable nucleation and growth region as Al_2O_3 became present as a second phase the thermal diffusivity increased with Al_2O_3 content there was an 11.7% increase in thermal diffusivity with a change in overall chemistry of 85.20 wt% Al_2O_3 to 87.71 wt% Al_2O_3 due to the drastic change in final chemistry 38.3 wt% Al_2O_3 caused by the nucleation and growth region in the system

while many materials undergo phase change at a fixed temperature soil systems exhibit a definite zone of phase change the variation of unfrozen water with temperature causes a soil system to freeze or thaw over a finite temperature range exact and approximate solutions are given for conduction phase change of plane layers of soil with unfrozen water contents that vary linearly and quadratically with temperature the temperature and phase change depths were found to vary significantly from those predicted for the constant temperature or Neumann problem the thermal conductivity and specific heat of the soil within the mushy zone varied as a function of unfrozen water content it was found that the effect of specific heat is negligible while the effect of variable thermal conductivity can be accounted for by a proper choice of thermal properties used in the constant thermal property solution

in many building envelopes actual thermal performance falls quite a bit short of nominal design parameters given in standards very often only windows doors and a small part of the wall area meet standards requirements in the other parts of the building envelope unaccounted thermal bridges reduce the effective thermal resistance of the insulation material such unaccounted heat losses compromise the thermal performance of the whole building envelope for the proper analysis of the thermal performance of most wall

and roof details measurements and three dimensional thermal modeling are necessary for wall thermal analysis the whole wall r value calculation method can be very useful in ties method thermal properties of all wall details are incorporated as an area weighted average for most wall systems the part of the wall that is traditionally analyzed is the clear wall that is the flat part of the wall that is uninterrupted by details it comprises only 50 to 80 of the total area of the opaque wall the remaining 20 to 50 of the wall area is not analyzed nor are its effects incorporated in the thermal performance calculations for most of the wall technologies traditionally estimated r values are 20 to 30 higher than whole wall r values such considerable overestimation of wall thermal resistance leads to significant errors in building heating and cooling load estimations in this paper several examples are presented of the use of the whole wall r value procedure for building envelope components the advantages of the use of the whole wall r value calculation procedure are also discussed for several building envelope components traditional clear wall r values are compared with the results of whole wall thermal analysis to highlight significant limits on the use of the traditional methods and the advantages of advanced computer modeling

the research presented in this dissertation focuses on the processing and thermomechanical properties of zrb₂ based ceramics the overall goal was to improve the understanding of thermal and mechanical properties based on processing conditions and additives to zrb₂ to achieve this the relationships between the thermal and mechanical properties were analyzed for zrb₂ ceramics that were densified by different methods varying amounts of carbon b₄c or tib₂ additions four main areas were investigated in this dissertation the first showed that decreased processing times regardless of densification method improved mechanical strength to 500 mpa this study also revealed that lower oxygen impurity contents led to less grain coarsening the second study showed that higher heating rates narrowed the grain size distribution which resulted in strengths above 600 mpa however the decreased processing times led to retention of zro₂ which decreased the thermal conductivity the third study revealed that carbon additions interacted with zro₂ and wc impurities introduced during powder processing to form zr w c which led to higher thermal conductivity than zrb₂ with no carbon added the last area examined the effect of solid solution additions on the electron and phonon contributions to thermal conductivity the formation of solid solutions decreased thermal conductivity to

Weak Solutions of a Phase-field Model for Phase Change of an Alloy with Thermal Properties 2020-11-25

the geothermal or ground source heat pump ghp has been shown to be a very efficient method of providing heating and cooling for buildings ghps exchange reject or extract heat with the earth by way of circulating water rather than by use of circulating outdoor air as with an air source heat pump the temperature of water entering a ghp is generally cooler than that of outdoor air when space cooling is required and warmer than that of outdoor air when space heating is required consequently the temperature lift across a ghp is less than the lift across an air source heat pump the lower temperature lift leads to greater efficiency higher capacity at extreme outdoor air temperatures and better indoor humidity control these benefits are achieved however at the cost of installing a ground heat exchanger in general this cost is proportional to length of the heat exchanger and for this reason there is an incentive to install the minimum possible length such that design criteria are met the design of a ground heat exchanger for a ghp system requires at a minimum the operating characteristics of the heat pumps estimates of annual and peak block loads for the building and information about the properties of the heat exchanger the size of the u tubes the grouting material etc the design also requires some knowledge of the thermal properties of the soil namely thermal conductivity thermal diffusivity and undisturbed soil temperature in the case of a vertical borehole heat exchanger bhex these properties generally vary with depth therefore in the design effective or average thermal properties over the length of the borehole are usually sought when the cost of doing so can be justified these properties are measured in an in situ experiment a test well is drilled to a depth on the same order as the expected depth of the heat pump heat exchangers a u tube heat exchanger is inserted and the borehole is grouted according to applicable state and local regulations water is heated and pumped through the u tube using a field generator to power the equipment or line voltage where available and the inlet and outlet water temperatures are measured as a function of time data on inlet and outlet temperature power input to the heater and pump and

water flow rate are collected at regular intervals typically 1 to 15 min for the duration of the experiment which may be as long as 60 h two common methods for determining soil thermal properties from such measurements are the line source method and the cylinder source method both are based on long term approximate solutions to the classical heat conduction problem of an infinitely long heat source in an infinite homogeneous medium although there are some differences in the way the two methods are implemented the only difference between the two models is whether the heat source is considered to be a line or a cylinder in both methods power input to the water loop is assumed to be constant the simplicity of these methods makes them attractive but they also have some disadvantages first of all because the line source and cylinder source approximations are inaccurate for early time behavior some of the initial data from the field test must be discarded the amount of data discarded can affect the property measurement also both methods assume that the heat transfer to the ground loop is constant in practice heat input to the loop may vary significantly over the course of a field test due to rough operation of the generator or short term sags and swells in power line voltage presumably this variation affects the accuracy of the thermal property measurement but error analysis is rarely performed this report presents a new method for determining thermal properties from short term in situ tests using a parameter estimation technique because it is based on numerical solutions to the heat conduction equation the new method is not affected by short term variations in heat input also since the model is accurate even for short times there is no need to discard initial data the parameter estimation technique used to determine the properties is based on statistical principles that provide quantitative estimates of measurement accuracy the parameter estimation method has now been tested with a laboratory test rig at oklahoma state university and in field tests at two elementary schools in lincoln nebraska using our estimation algorithms and building on the validation achieved during testing we have developed a computer program the geothermal properties measurement gpm model that allows users to determine thermal properties from short term in situ field tests this program is currently available free of charge
