entire functions of several complex variables constitute an important and original chapter in complex analysis the study is often motivated by certain applications to specific problems in other areas of mathematics partial differential equations via the fourier laplace transformation and convolution operators analytic number theory and problems of transcendence or approximation theory just to name a few what is important for these applications is to find solutions which satisfy certain growth conditions the specific problem defines inherently a growth scale and one seeks a solution of the problem which satisfies certain growth conditions on this scale and sometimes solutions of minimal asymptotic growth or optimal solutions in some sense for one complex variable the study of solutions with growth conditions forms the core of the classical theory of entire functions and historically the relationship between the number of zeros of an entire function  $f(z)$  of one complex variable and the growth of  $|f(z)|$  or equivalently  $\log |f(z)|$  was the first example of a systematic study of growth conditions in a general setting problems with growth conditions on the solutions demand much more precise information than existence theorems the correspondence between two scales of growth can be interpreted often as a correspondence between families of bounded sets in certain frechet spaces however for applications it is of utmost importance to develop precise and explicit representations of the solutions

the method of fractional steps known familiarly as the method of splitting is a remarkable technique developed by n n yanenko and his collaborators for solving problems in theoretical mechanics numerically it is applicable especially to potential problems problems of elasticity and problems of fluid dynamics most of the applications at the present time have been to incompressible flow with free boundaries and to viscous flow at low speeds the method offers a powerful means of solving the navier stokes equations and the results produced so far cover a range of reynolds numbers far greater than that attained in earlier methods further development of the method should lead to complete numerical solutions of many of the boundary layer and

wake problems which at present defy satisfactory treatment as noted by the author very few applications of the method have yet been made to problems in solid mechanics and prospects for answers both in this field and other areas such as heat transfer are encouraging as the method is perfected it is likely to supplant traditional relaxation methods and finite element methods especially with the increase in capability of large scale computers the literal translation was carried out by t cheron with financial support of the northrop corporation the editing of the translation was undertaken in collaboration with n n yanenko and it is a plea sure to acknowledge his patient help and advice in this project the edited manuscript was typed for the most part by mrs
